intro

II.   BERRY CURVATURE IN RECIPROCAL SPACE

A.   Berry Curvature

When the Hamiltonian of a system has a paramater $\boldsymbol{\lambda}$ which evolves slowly (compared to the timescale $\frac{\hbar}{\varepsilon}$ of a state $|\varepsilon\rangle$), an eigenstate of the Hamiltonian evolves as ([1], see Appendix A for derivation),

$$|\varepsilon(\boldsymbol{\lambda}(t))\rangle = e^{i\gamma(t)} e^{-\frac{i}{\hbar}\int_0^t \varepsilon(\boldsymbol{\lambda}(t'))dt'} |\varepsilon(\boldsymbol{\lambda}(0))\rangle \tag{1}$$

where the geometric phase $\gamma(t)$ is given by $i\int_{\boldsymbol{\lambda}_i}^{\boldsymbol{\lambda}_f} \langle\varepsilon(\boldsymbol{\lambda})|\nabla_{\boldsymbol{\lambda}}|\varepsilon(\boldsymbol{\lambda})\rangle \cdot d\boldsymbol{\lambda}$. It depends on the trajectory in the parameter space $\boldsymbol{\lambda}$, not just the endpoints. The real quantity $i\langle\varepsilon(\boldsymbol{\lambda})|\nabla_{\boldsymbol{\lambda}}|\varepsilon(\boldsymbol{\lambda})\rangle = \boldsymbol{A}(\boldsymbol{\lambda})$ is known as the Berry connection, and its curl, $\boldsymbol{\Omega} = \nabla_{\boldsymbol{\lambda}} \times \boldsymbol{A}$ is known as the Berry curvature.

Note: $\langle\varepsilon(\boldsymbol{\lambda})|\nabla_{\boldsymbol{\lambda}}|\varepsilon(\boldsymbol{\lambda})\rangle$ stands for $\int d\boldsymbol{r}\varepsilon_{\boldsymbol{\lambda}}^*(\boldsymbol{r})\nabla_{\boldsymbol{\lambda}}\varepsilon_{\boldsymbol{\lambda}}(\boldsymbol{r})$, where $\varepsilon_{\boldsymbol{\lambda}}(\boldsymbol{r})$ is the normalized position space wavefunction of $|\varepsilon(\boldsymbol{\lambda})\rangle$.

While the overall phase of the state does not affect its physical observables, if we take a linear combination of such eigenstates, each of them would evolve with a different geometric phase, and that would indeed affect the physical properties of the system. We would now see how such a geometric phase manifests in electrons moving in a lattice, when an external electromagnetic field is applied.

B.   Electrons in a lattice

Now, let us consider an electron in a periodic potential $V(\boldsymbol{r})$ (e.g. the potential due to a lattice), without any external fields. The Hamiltonian describing it is given by $\hat{H} = \frac{\hat{\boldsymbol{p}}^2}{2m} + V(\hat{\boldsymbol{r}})$.

The eigenfunctions of this Hamiltonian are of the form,

$$\psi_{n,\boldsymbol{k}}(\boldsymbol{r}) = e^{i\boldsymbol{k}\cdot\boldsymbol{r}} u_{n,\boldsymbol{k}}(\boldsymbol{r})$$

Here $u_{n,\boldsymbol{k}}(\boldsymbol{r})$ is a function with the same periodicity as $V(\boldsymbol{r})$ (e.g. in a lattice, it would be periodic in every unit cell). The quantity $\hbar\mathbf{k}$ is known as the crystal momentum and n is the band index. This result is known as Bloch's theorem (See chapter 8 of [?]). The crystal momentum is a good quantum number for an electron in a lattice, and it is conserved upto a reciprocal lattice vector (times $\hbar$). Now, we can rewrite the eigenvalue equation $\hat{H}\psi_{n,\boldsymbol{k}}(\boldsymbol{r}) = \varepsilon_{n,\boldsymbol{k}}\psi_{n,\boldsymbol{k}}(\boldsymbol{r})$ as,

$$\left[\frac{\hbar^2}{2m}(\boldsymbol{k} - i\nabla)^2 + V(\boldsymbol{r})\right] u_{n,\boldsymbol{k}}(\boldsymbol{r}) = \varepsilon_{n,\boldsymbol{k}} u_{n,\boldsymbol{k}}(\boldsymbol{r}) \tag{2}$$

In this equation, $\boldsymbol{k}$ is just a parameter in the effective Hamiltonian. When we apply an external electromagnetic field, the crystal momentum is not anymore a good quantum number. Its evolution is governed by the Lorenz force, (See Appendix B for derivation)

$$\boxed{\hbar\dot{\boldsymbol{k}} = -e\left(\boldsymbol{E} + \langle\dot{\boldsymbol{r}}\rangle \times \boldsymbol{B}\right)} \tag{3}$$

As $\boldsymbol{k}$ changes, it would give rise to a geometric phase. After a small time interval Δt, $\boldsymbol{k}$ would evolve to $\boldsymbol{k} + \Delta\boldsymbol{k}$ (with $\Delta\boldsymbol{k} = \dot{\boldsymbol{k}}\Delta t$), and the wavefunction of a state labeled with $\boldsymbol{k}$ would evolve as

$$u_{n,\boldsymbol{k}} \to e^{i\boldsymbol{A}\cdot\Delta\boldsymbol{k}} e^{-i\frac{\varepsilon_{\boldsymbol{k}}\Delta t}{\hbar}} u_{n,\boldsymbol{k}+\Delta\boldsymbol{k}} \tag{4}$$

, where $\boldsymbol{A}(\boldsymbol{k}) = i\langle u_{n,\boldsymbol{k}}|\nabla_{\boldsymbol{k}}|u_{n,\boldsymbol{k}}\rangle$ is the Berry connection in the reciprocal space. Again, for a state labeled with a single $\boldsymbol{k}$, this geometric phase is an overall global phase, which would not show up in physical observables. However, if we take a linear superposition of Bloch wavefunctions with different values of $\boldsymbol{k}$, each of them would evolve with a different geometric phase $\gamma_n(\boldsymbol{k}) = \int_0^t dt' \boldsymbol{A}(\boldsymbol{k}) \cdot \frac{d\boldsymbol{k}}{dt'}$, and we would soon see that the interference of such phase factors would lead to many interesting effects.

III.   EFFECTS OF BERRY CURVATURE

A.   Modification of semiclassical equations of motion of a wavepacket

The probability density of the wavefunction $\psi_{n,\boldsymbol{k}}(\boldsymbol{r}) = e^{i\boldsymbol{k}\cdot\boldsymbol{r}}u_{n,\boldsymbol{k}}(\boldsymbol{r})$ is not localized anywhere, it is periodic over all unit cells (the blue curve in Fig. 1). We can construct a wave packet by forming a linear superposition of many such states, such that the wavepacket is localized at some point $\boldsymbol{r}_0$ in the real space, and its crystal momentum is also localized around a value of $\hbar\boldsymbol{k}_0$.

Although this wavepacket is localized in both real space and (crystal) momentum space, it does not violate Heisenberg's uncertainty relation, because for this wave packet, the product of the uncertainties in position and (crystal) momentum, $\Delta\boldsymbol{r}\Delta\boldsymbol{k}$ is still greater than 1. While the wavepacket is spread over many unit cells, its spatial variation $\Delta\boldsymbol{r}$ is much smaller than the dimensions of the system, and $\Delta\boldsymbol{k}$ is much smaller than $\langle\boldsymbol{k}\rangle = \boldsymbol{k}_0$, and the dimensions of the Brillouin zone. As a result, in laboratory scale, the wavepacket behaves like a classical particle, with an almost localized value of position and crystal momentum.

FIG. 1. **Need to update caption**

It can be shown [2] that for such a wavepacket, the expectation value position of its center evolves as,

$$\boxed{\langle\dot{\boldsymbol{r}}\rangle = \frac{1}{\hbar}\nabla_{\boldsymbol{k}}\varepsilon_{\boldsymbol{k}} - \langle\dot{\boldsymbol{k}}\rangle \times \boldsymbol{\Omega}(\boldsymbol{k})} \tag{5}$$

Here, $\boldsymbol{\Omega}(\boldsymbol{k}) = \nabla_{\boldsymbol{k}} \times \boldsymbol{A}(\boldsymbol{k})$ is the Berry curvature in the reciprocal space. In popular Solid State Physics textbooks, the second term in the RHS in Eq. (5), involving the Berry curvature is omitted (e.g. see Eq. 8.51 of [?]). This is most likely because people thought that the overall phase factor is unimportant. Also, we would soon see that the Berry curvature is identically zero unless certain symmetries are broken, and this is why its effects cannot be observed in most systems.

To see why the extra term appears, let us first investigate how we can produce such a wavepacket, which is localized in both position and crystal momentum space. This discussion is based on Section I. of [2]. To make the wavepacket localized near $\boldsymbol{k}_0$ in the reciprocal space, consider a *real* weight function $w(\boldsymbol{k} - \boldsymbol{k}_0)$, which is sharply localized about $\boldsymbol{k} = \boldsymbol{k}_0$. Now consider a linear superposition of the Bloch wavefunctions, of the form, $\int d\boldsymbol{k}w(\boldsymbol{k}-\boldsymbol{k}_0)e^{-i\boldsymbol{k}\cdot\boldsymbol{r}_0}\left(e^{i\boldsymbol{k}\cdot\boldsymbol{r}}u_{n,\boldsymbol{k}}\boldsymbol{r}\right)$. The expectation value of $\boldsymbol{k}$ of this wavefunction should be localized about $\boldsymbol{k}_0$. Then, near $\boldsymbol{r} = \boldsymbol{r}_0$, the functions $e^{i\boldsymbol{k}\cdot(\boldsymbol{r}-\boldsymbol{r}_0)}$ constructively interfere, and we would expect the wavepacket to have a high probability density at $\boldsymbol{r}_0$. However, the functions $u_{n,\boldsymbol{k}}(\boldsymbol{r})$ may have different phases for different values of $\boldsymbol{k}$ at the same $\boldsymbol{r} = \boldsymbol{r}_0$, and then the waves would not constructively interfere. After properly taking account of this, the wavefunction that is localized around $\langle\boldsymbol{r}\rangle = \boldsymbol{r}_0$, and peaked at crystal momentum $\hbar\boldsymbol{k}_0$ is,

$$\psi(\boldsymbol{r}, t = 0) = \int d\boldsymbol{k}w(\boldsymbol{k} - \boldsymbol{k}_0)e^{i\boldsymbol{A}(\boldsymbol{k_0})\cdot(\boldsymbol{k}-\boldsymbol{k}_0)}e^{-i\boldsymbol{k}\cdot\boldsymbol{r}_0}\left(e^{i\boldsymbol{k}\cdot\boldsymbol{r}}u_{n,\boldsymbol{k}}(\boldsymbol{r})\right)$$

Here $\boldsymbol{A}$ is again the Berry connection. After a small time Δt, the individual Bloch wavefunctions would then evolve as in Eq. (4), and the wavefunction of the wavepacket would be,

$$\psi(\boldsymbol{r}, t = \Delta t) = \int d\boldsymbol{k}w(\boldsymbol{k} - \boldsymbol{k}_0)e^{i\boldsymbol{A}(\boldsymbol{k_0})\cdot(\boldsymbol{k}-\boldsymbol{k}_0)}e^{-i\boldsymbol{k}\cdot\boldsymbol{r}_0}\left(e^{i(\boldsymbol{k}+\Delta\boldsymbol{k})\cdot\boldsymbol{r}}e^{i\boldsymbol{A}\cdot\Delta\boldsymbol{k}}e^{-i\frac{\varepsilon_{\boldsymbol{k}}\Delta t}{\hbar}}u_{n,\boldsymbol{k}+\Delta\boldsymbol{k}}\right)$$

It can be shown (See Appendix. C 1), that for this state, the expectation value of position is located at

$$\langle\boldsymbol{r}\rangle = \boldsymbol{r}_0 + \frac{\Delta t}{\hbar}\nabla_{\boldsymbol{k}}\varepsilon_{\boldsymbol{k}}|_{\boldsymbol{k}=\boldsymbol{k}_0} - \Delta\boldsymbol{k}_0 \times \boldsymbol{\Omega}(\boldsymbol{k_0})$$

After dividing the shift in $\langle r \rangle$ by Δt, Eq. (5) follows.

B. Violation of Liouville's theorem and Modification of phase space density

Consider a point $(\boldsymbol{r}, \boldsymbol{k})$ in the phase space, with a small volume element ΔV around it. We now drop the notation $\langle \cdot \rangle$ of expectation values, and denote $\langle \boldsymbol{r} \rangle \equiv \boldsymbol{r}$ and $\langle \boldsymbol{k} \rangle \equiv \boldsymbol{k}$ for a wavepacket The points inside ΔV evolve as governed by the semiclassical equations of motion,

$$\boxed{\dot{\boldsymbol{r}} = \frac{1}{\hbar} \nabla_{\boldsymbol{k}} \varepsilon_{\boldsymbol{k}} - \dot{\boldsymbol{k}} \times \boldsymbol{\Omega}(\boldsymbol{k})} \tag{6}$$

$$\boxed{\hbar \dot{\boldsymbol{k}} = -e \left(\boldsymbol{E} + \dot{\boldsymbol{r}} \times \boldsymbol{B} \right)} \tag{7}$$

and suppose, they occupy a new volume $\Delta V(t)$ around the point $(\boldsymbol{r}', \boldsymbol{k}')$ after time t. Then, the quantity

$$\Delta V(t) \left(1 + \frac{e}{\hbar} \boldsymbol{B} \left(\boldsymbol{r}(t) \right) \cdot \boldsymbol{\Omega} \left(\boldsymbol{k}(t) \right) \right)$$

remains a constant of motion (See Appendix D).

Liouville's theorem states that the volume ΔV occupied by a fixed number of points in the phase space remains invariant (in other words, the phase space density remains invariant). Here, that does not hold anymore (unless either of $\boldsymbol{B}$ or $\boldsymbol{\Omega}$ is zero). Note that the quantity defined above is a function of the local coordinates $(\boldsymbol{r}(t), \boldsymbol{k}(t))$, and does not depend on the trajectory.

As a result, when we calculate the expecation value of any operator $\mathcal{O}$, we would have to introduce an additional factor of $\left(1 + \frac{e}{\hbar} \boldsymbol{B} \left(\boldsymbol{r}(t) \right) \boldsymbol{\Omega} \left(\boldsymbol{k}(t) \right) \right)$ in the integrand, as follows.

$$\langle \mathcal{O} \rangle = \int \frac{d\boldsymbol{k}}{(2\pi)^d} \left(1 + \frac{e}{\hbar} \boldsymbol{B} \left(\boldsymbol{r}(t) \right) \cdot \boldsymbol{\Omega} \left(\boldsymbol{k}(t) \right) \right) \langle \mathcal{O} \rangle_{\boldsymbol{k}}$$

Also, since Liouville's theorem does not hold anymore, we cannot obtain the equations of motion (6), (7) from any effective Hamiltonian.

IV. VALIDITY OF THIS THEORY WHEN THE EFFECTIVE HAMILTONIAN DOES NOT COMMUTE WITH ITSELF AT DIFFERENT TIMES

The effective Hamiltonian $\left[\frac{\hbar^2}{2m} (\boldsymbol{k} - i\nabla)^2 + V(\boldsymbol{r}) \right]$ does not commute with itself for different values of $\boldsymbol{k}$. Then, form of the phase factor in Eq. (1) . However, the contribution of the non-zero commutator is $\mathcal{O} \left(\Delta t^2 \right)$ (need to show this explicitly), and does not effect the semiclassical equations of motion.

V. DECOUPLING OF THE EQUATIONS OF MOTION AND THEIR SIMPLIFICATION

$$\dot{\mathbf{r}} = \frac{\frac{1}{\hbar} \frac{\partial \varepsilon}{\partial \mathbf{k}} + \frac{e}{\hbar} (\mathbf{E} \times \boldsymbol{\Omega}) + \frac{e}{\hbar^2} (\boldsymbol{\Omega} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}}) \mathbf{B}}{1 + \frac{e}{\hbar} \mathbf{B} \cdot \boldsymbol{\Omega}} \tag{8}$$

$$\dot{\mathbf{k}} = -\frac{\frac{e}{\hbar} \mathbf{E} + \frac{e}{\hbar^2} \frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B} + \frac{e^2}{\hbar^2} (\mathbf{E} \cdot \mathbf{B}) \boldsymbol{\Omega}}{1 + \frac{e}{\hbar} \mathbf{B} \cdot \boldsymbol{\Omega}} \tag{9}$$

In a 2D sample, $\boldsymbol{\Omega}$ is along the z axis, while $\frac{\partial \varepsilon}{\partial \mathbf{k}}$ is in the xy plane, then $\boldsymbol{\Omega} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}} = 0$.

Also, if we take perpendicular electric and magnetic fields, then $\mathbf{E} \cdot \mathbf{B} = 0$.

Then the equations (8) and (9) simplify to,

$$\dot{\mathbf{r}} = \frac{\frac{1}{\hbar}\frac{\partial \varepsilon}{\partial \mathbf{k}} + \frac{e}{\hbar}(\mathbf{E} \times \boldsymbol{\Omega})}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}} \tag{10}$$

$$\dot{\mathbf{k}} = -\frac{\frac{e}{\hbar}\mathbf{E} + \frac{e}{\hbar^2}\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B}}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}} \tag{11}$$

VI.   STRATEGY OF CALCULATION OF THERMAL AND HEAT CURRENTS

A.   Equilibrium and Non-Equilibrium distribution functions

VII.   BOLTZMANN TRANSPORT EQUATION AND ITS SOLUTION

Some discussions about the relaxation time approximation....

Under the relaxation time approximation, the Boltzmann Transport Equation (BTE) takes the form

$$\dot{\mathbf{k}} \cdot \frac{\partial}{\partial \mathbf{k}}(f + g) + \dot{\mathbf{r}} \cdot \frac{\partial}{\partial \mathbf{r}}(f + g) = -\frac{g}{\tau} \tag{12}$$

,

which can be cast into the form

$$\frac{g}{\tau} + \dot{\mathbf{k}} \cdot \frac{\partial}{\partial \mathbf{k}}g + \dot{\mathbf{r}} \cdot \frac{\partial}{\partial \mathbf{r}}g = -\dot{\mathbf{k}} \cdot \frac{\partial}{\partial \mathbf{k}}f - \dot{\mathbf{r}} \cdot \frac{\partial}{\partial \mathbf{r}}f \tag{13}$$

.

Here $f = \frac{1}{e^{\beta(\varepsilon_{\mathbf{k}} - \mu)} + 1}$ is the equilibrium Fermi distribution, and g is the non-equilibrium part. Using the decoupled equations of motion, right hand side of Eq. (13) simplifies to (*Need to show the steps*),

$$\frac{\partial f}{\partial \varepsilon}\frac{1}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}}\frac{1}{\hbar}\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \left[e\mathbf{E} + \nabla\mu + \nabla T\frac{\varepsilon - \mu}{T}\right]$$

.

When the fields are constant in space and time, we assume that $\frac{\partial g}{\partial \mathbf{r}} = 0$.

Validity of the assumption: When we solve the equation after discarding this term, we would find that (See Eq. (15)) this term is second order in the applied fields. Then upto linear order, we can discard this term.

Then, the BTE becomes, $\frac{g}{\tau} - \frac{\frac{e}{\hbar}\mathbf{E} + \frac{e}{\hbar^2}\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B}}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}} \cdot \frac{\partial}{\partial \mathbf{k}}g = \frac{\partial f}{\partial \varepsilon}\frac{1}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}}\frac{1}{\hbar}\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \left[e\mathbf{E} + \nabla\mu + \nabla T\frac{\varepsilon - \mu}{T}\right]$

A.   Solution for $\mathbf{B} \neq 0$, $\boldsymbol{\Omega} \neq 0$, $\mathbf{E} \neq 0$, $\nabla\mu = \nabla T = 0$

In this limit, the equation becomes,

$$\frac{g}{\tau} - \frac{\frac{e}{\hbar}\mathbf{E} + \frac{e}{\hbar^2}\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B}}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}} \cdot \frac{\partial}{\partial \mathbf{k}}g = \frac{\partial f}{\partial \varepsilon}\frac{1}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}}\frac{1}{\hbar}\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot e\mathbf{E}$$

If we discard the term $\mathbf{E} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}}$ in the LHS, we would find that g is a linear function of $\mathbf{E}$. Then, $\mathbf{E} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}}$ would be quadratic in $\mathbf{E}$. This is why, we can discard this term. (This is not a circular argument. If we do this, everything remains self consistent upto linear order)

Then, the equation takes the form,

$$\frac{g}{\tau} - \frac{\frac{e}{\hbar^2}}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}}\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B} \cdot \frac{\partial}{\partial \mathbf{k}}g = \frac{\partial f}{\partial \varepsilon}\frac{1}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}}\frac{1}{\hbar}\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot e\mathbf{E} \tag{14}$$

We solve this equation, treating the second term in LHS as a perturbation (See Appendix E). We write $g = g_0 + g_1$, such that $\frac{g_0}{\tau} = \frac{\partial f}{\partial \varepsilon}\frac{1}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}}\frac{1}{\hbar}\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot e\mathbf{E}$, and $\frac{g_1}{\tau} - \frac{\frac{e}{\hbar^2}}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}}\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B} \cdot \frac{\partial}{\partial \mathbf{k}}g_0 = 0$. Then, g_1 is a linear function of $\mathbf{B}$, and it is justified to discard the term $\frac{\frac{e}{\hbar^2}}{1 + \frac{e}{\hbar}\mathbf{B} \cdot \boldsymbol{\Omega}}\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B} \cdot \frac{\partial}{\partial \mathbf{k}}g_1$, as it would be quadratic in $\mathbf{B}$

Then, $g_0 = \frac{\partial f}{\partial \varepsilon} \frac{1}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \frac{e\tau}{\hbar} \frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \mathbf{E}$. To find g_1, we need to calculate $\frac{\partial g_0}{\partial \mathbf{k}}$, i.e., the quantity $\frac{\partial}{\partial \mathbf{k}} \left[\frac{\partial f}{\partial \varepsilon} \frac{1}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \frac{e\tau}{\hbar} \frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \mathbf{E} \right]$.

To calculate it, let us first calculate $\nabla \left[\phi \mathbf{A} \cdot \mathbf{C} \right]$, where ϕ is a scalar function, $\mathbf{A}$ is a vector function, and $\mathbf{C}$ is a constant vector.

$\nabla \left[\phi \mathbf{A} \cdot \mathbf{C} \right] = (\nabla \phi)(\mathbf{A} \cdot \mathbf{C}) + \phi(\mathbf{C} \cdot \nabla)A + \phi(\mathbf{C} \times (\nabla \times \mathbf{A}))$. In our calculation, $\phi \sim \frac{\partial f}{\partial \varepsilon} \frac{1}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \frac{e\tau}{\hbar}$, $\mathbf{A} \sim \frac{\partial \varepsilon}{\partial \mathbf{k}}$, and $\mathbf{C} \sim \mathbf{E}$.

Then,

$$\frac{\partial}{\partial \mathbf{k}} \left[\frac{\partial f}{\partial \varepsilon} \frac{1}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \frac{e\tau}{\hbar} \frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \mathbf{E} \right] = \frac{\partial}{\partial \mathbf{k}} \left[\frac{\frac{\partial f}{\partial \varepsilon}\tau}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \right] \frac{e\mathbf{E}}{\hbar} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}} + \frac{\frac{\partial f}{\partial \varepsilon}\tau}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \left[(\frac{e}{\hbar}\mathbf{E} \cdot \frac{\partial}{\partial \mathbf{k}})\frac{\partial \varepsilon}{\partial \mathbf{k}} + \frac{e}{\hbar}\mathbf{E} \times (\frac{\partial}{\partial \mathbf{k}} \times \frac{\partial \varepsilon}{\partial \mathbf{k}}) \right]$$

.

The last term is zero because it is the curl of a gradient, $\frac{\partial}{\partial \mathbf{k}} \times \frac{\partial \varepsilon}{\partial \mathbf{k}} = \nabla_{\mathbf{k}} \times (\nabla_{\mathbf{k}} \varepsilon) = 0$.

Finally,

$$g = \frac{\partial f}{\partial \varepsilon} \frac{1}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \frac{\tau}{\hbar} \frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot e\mathbf{E} + \frac{\frac{e\tau}{\hbar^2}}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \mathbf{B} \times \left[\frac{\partial}{\partial \mathbf{k}} \left[\frac{\frac{\partial f}{\partial \varepsilon}\tau}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \right] \frac{e\mathbf{E}}{\hbar} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}} + \frac{\frac{\partial f}{\partial \varepsilon}\tau}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \left[(\frac{e}{\hbar}\mathbf{E} \cdot \frac{\partial}{\partial \mathbf{k}})\frac{\partial \varepsilon}{\partial \mathbf{k}} \right] \right] \quad (15)$$

Verification: When $\mathbf{\Omega} = 0$, and $\varepsilon = \frac{\hbar^2 k^2}{2m^*}$, this term produces $\sigma_{xy} = -\omega_c \tau \frac{ne^2\tau}{m^*}$. (*Need to show the steps*)

B. Solution for $\mathbf{B} \neq 0$, $\mathbf{\Omega} \neq 0$, $\mathbf{E} = 0$, $\nabla\mu \neq 0$, $\nabla T \neq 0$

Here

$$\dot{\mathbf{r}} = \frac{\frac{1}{\hbar}\frac{\partial \varepsilon}{\partial \mathbf{k}}}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \quad (16)$$

$$\dot{\mathbf{k}} = -\frac{\frac{e}{\hbar^2}\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B}}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \quad (17)$$

We again take $\frac{\partial g}{\partial \mathbf{k}} \sim 0$.

Under these circumstances, the equation becomes,

$$\frac{g}{\tau} - \frac{\frac{e}{\hbar^2}\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B}}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \cdot \frac{\partial}{\partial \mathbf{k}} g = \frac{\partial f}{\partial \varepsilon} \frac{1}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \frac{1}{\hbar} \frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \left[\nabla\mu + \nabla T \frac{\varepsilon - \mu}{T} \right]$$

Let $g = g_0 + g_1$, with $g_0 = \frac{\partial f}{\partial \varepsilon} \frac{1}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \frac{\tau}{\hbar} \frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \left[\nabla\mu + \nabla T \frac{\varepsilon-\mu}{T} \right]$ and $\frac{g_1}{\tau} - \frac{\frac{e}{\hbar^2}\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B}}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \cdot \frac{\partial}{\partial \mathbf{k}} g_0 = 0$

Then, (*Need to show the steps*)

$$\frac{\partial g_0}{\partial \mathbf{k}} = \frac{\partial}{\partial \mathbf{k}} \left[\frac{\frac{\partial f}{\partial \varepsilon}\tau}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \right] \frac{\nabla\mu + \frac{\varepsilon-\mu}{T}}{\hbar} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}} + \frac{\frac{\partial f}{\partial \varepsilon}\tau}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \left[(\frac{\nabla\mu + \frac{\varepsilon-\mu}{T}}{\hbar} \cdot \frac{\partial}{\partial \mathbf{k}})\frac{\partial \varepsilon}{\partial \mathbf{k}} + \frac{1}{\hbar}(\nabla\mu + \frac{\varepsilon-\mu}{T}) \times \underbrace{(\frac{\partial}{\partial \mathbf{k}} \times \frac{\partial \varepsilon}{\partial \mathbf{k}})}_{0} \right]$$

$$+ \frac{\frac{\partial f}{\partial \varepsilon}\tau}{1+\frac{e}{\hbar}\mathbf{B}\cdot\mathbf{\Omega}} \left[\frac{1}{\hbar}(\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \frac{\partial}{\partial \mathbf{k}})(\frac{\varepsilon\nabla T}{T}) + \frac{1}{\hbar}\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \left(\frac{\partial}{\partial \mathbf{k}} \times \left(\frac{\varepsilon\nabla T}{T} \right) \right) \right]$$

The term inside the final third bracket can be further simplified.

$$(\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \frac{\partial}{\partial \mathbf{k}})(\frac{\varepsilon\nabla T}{T}) + \frac{\partial \varepsilon}{\partial \mathbf{k}} \times \left(\frac{\partial}{\partial \mathbf{k}} \times \left(\frac{\varepsilon\nabla T}{T} \right) \right) = (\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}})(\frac{\nabla T}{T}) + \frac{\partial \varepsilon}{\partial \mathbf{k}} \times \left(\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \left(\frac{\nabla T}{T} \right) \right)$$

$$= (\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}})(\frac{\nabla T}{T}) + \left(\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \frac{\nabla T}{T} \right) \frac{\partial \varepsilon}{\partial \mathbf{k}} - (\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}})(\frac{\nabla T}{T})$$

$$= \left(\frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \frac{\nabla T}{T} \right) \frac{\partial \varepsilon}{\partial \mathbf{k}}$$

.

When we calculate $g_1 = \tau \frac{\frac{e}{\hbar^2} \frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B}}{1 + \frac{e}{\hbar} \mathbf{B} \cdot \mathbf{\Omega}} \cdot \frac{\partial}{\partial \mathbf{k}} g_0$, this term cancels because $\frac{\partial \varepsilon}{\partial \mathbf{k}} \times \mathbf{B} \frac{\partial \varepsilon}{\partial \mathbf{k}} = 0$.
Finally we get,

$$g = \frac{\partial f}{\partial \varepsilon} \frac{1}{1 + \frac{e}{\hbar} \mathbf{B} \cdot \mathbf{\Omega}} \frac{\tau}{\hbar} \frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \mathbf{S} + \frac{\frac{e\tau}{\hbar^2}}{1 + \frac{e}{\hbar} \mathbf{B} \cdot \mathbf{\Omega}} \frac{\partial \varepsilon}{\partial \mathbf{k}} \cdot \mathbf{B} \times \left[\frac{\partial}{\partial \mathbf{k}} \left[\frac{\frac{\partial f}{\partial \varepsilon} \tau}{1 + \frac{e}{\hbar} \mathbf{B} \cdot \mathbf{\Omega}} \right] \frac{\mathbf{S}}{\hbar} \cdot \frac{\partial \varepsilon}{\partial \mathbf{k}} + \frac{\frac{\partial f}{\partial \varepsilon} \tau}{1 + \frac{e}{\hbar} \mathbf{B} \cdot \mathbf{\Omega}} \left[(\frac{1}{\hbar} \mathbf{S} \cdot \frac{\partial}{\partial \mathbf{k}}) \frac{\partial \varepsilon}{\partial \mathbf{k}} \right] \right] \quad (18)$$

with $\mathbf{S} = \nabla \mu + \frac{\varepsilon - \mu}{T}$.
Einstein and Onsager relations are perfectly valid.

VIII. EINSTEIN AND ONSAGER RELATIONS

Their apparent violations (when $\mathbf{\Omega} \neq 0$) and the resolution with magnetization currents.

IX. CHERN NUMBER IN DIFFERENT MODELS

A. Monolayer and Bilayer Graphene

B. Selective Valley Population

C. Valley Chern Number

D. Calculation of Effective Hamiltonian and its Chern Number

X. NEW RESULTS

1. Expression of electric and thermal Conductivity tensors when both Magnetic field and Berry Curvature are present (upto linear order in Magnetic field)
2. A condition on the energy magnetization that needs to hold for anomalous thermal current to satisfy the Einstein relation.

Appendix A: Calculation of Berry Phase

text

Appendix B: Time evolution of Crystal Momentum

text

Appendix C: Calculation of expectation value of the position of the wavepacket

Then, to take account of this, let us consider the wavefunction,

$$\phi_{\mathbf{X}}(\mathbf{r}, t = 0) = \int d\mathbf{k} w(\mathbf{k} - \mathbf{k}_0) e^{i \mathbf{X}(\mathbf{k_0}) \cdot (\mathbf{k} - \mathbf{k}_0)} e^{-i \mathbf{k} \cdot \mathbf{r}_0} \left(e^{i \mathbf{k} \cdot \mathbf{r}} u_{n, \mathbf{k}}(\mathbf{r}) \right)$$

For this wavefunction,

$$\langle \mathbf{r} \rangle_{\phi_{\mathbf{X}}} = \langle \phi_X(\mathbf{r}, t = 0) | \mathbf{r} | \phi_X(\mathbf{r}, t = 0) \rangle = \mathbf{r}_0 - \mathbf{X}(\mathbf{k_0}) + \mathbf{A}(\mathbf{k_0})$$

where $\mathbf{A}(\mathbf{k_0})$ is the Berry connection. Then, for the wavepacket to be centered at $\mathbf{r} = \mathbf{r}_0$, we need to take $\mathbf{X} = \mathbf{A}$.

1. Calculation of Expectation value of the time evolved wavepacket

Appendix D: Evolution of phase space volume

Appendix E: Validity of this perturbation theory

Classically, $\dot{\mathbf{k}} \cdot \frac{\partial}{\partial \mathbf{k}} g \sim \dot{\mathbf{p}} \cdot \frac{\partial}{\partial \mathbf{p}} g \sim e(\mathbf{v} \times B) \cdot \frac{\partial}{m \partial \mathbf{v}} g \sim \boldsymbol{\omega} \times \mathbf{v} \cdot \frac{\partial g}{\partial \mathbf{v}} \sim \omega g$.

When $\omega \ll \frac{1}{\tau}$ (in the limit of low magnetic field), it is justified to treat ωg as a perturbation over $\frac{g}{\tau}$, in the LHS of Eq. (13).

1. How low magnetic is 'low'?

For $\omega = \frac{1}{\tau}$, $B_{crit} = \frac{m^*}{\tau e}$, and a magnetic field much lower than this qualifies as a "low" magnetic field. If we take $m^* = m_e$ and $\tau \sim 10^{-14} s$ (chapter 3 of [3]), $B_{crit} \sim 570 T$ (which is found in a typical metal), which is order of magnitudes above the magnetic field accessible in labs. In typical metals, $m^* > m_e$, the bare electron mass, and the critical magnetic field is even higher.

In very clean samples, τ can be as high as $10^{-12} s$, and even there, the critical magnetic field would be $5.7 T$, which too is hard to achieve in most labs.

Conclusion: Unless the sample is very clean, the magnetic fields produced in labs qualify as "low", and in this regime, this perturbation theory remains valid.
